Read, mostly understood.

## 2 Spinning Closed String in AdS Space:

For a classical spinning string, we have Nambu–Goto action:

$$S_{NG} = -T \int d\tau \, d\sigma \, \sqrt{-\det \gamma_{ab}}, \quad \gamma_{ab} = G_{\mu\nu} \partial_a X^{\mu} \partial_b X^{\nu}$$
 (1)

Here  $G_{\mu\nu}$  is the spacetime metric.  $\gamma_{ab}$  can be treated as the induced metric on the worldsheet.

In AdS space we have:

$$ds^{2} = R^{2} \left( -\cosh^{2}\rho \,dt^{2} + d\rho^{2} + \sinh^{2}\rho \,d\Omega^{2} \right) \tag{2}$$

Where  $d\Omega^2$  is the metric of a unit (d-2)—sphere  $S^{d-2}$ . For convenience let's define unit  $S^{d-2}$  metric  $G^1_{ij}$ , and raise or lower the  $i, j, \cdots$  indices using  $G^1_{ij}$  instead of  $G_{ij}$ , i.e.,

$$G_{ij}^1 = G_{ij} / (R^2 \sinh^2 \rho), \quad i, j = 2, \cdots, d-1$$
 (3)

Furthermore, we consider the special case that the closed string is *folded*, like a rubber band stretched along a line; in this case we can choose the worldsheet parameter  $(\tau, \sigma) = (t, \rho)$  while  $\Omega = \Omega(t, \rho) = \Omega(\tau, \sigma)$ , which leads to the following decomposition:

$$\partial_{a}X^{\mu} = \delta_{a}^{\mu} + \delta_{i}^{\mu} \partial_{a}\Omega^{i}, \quad a = 0, 1, \quad i = 2, \cdots, d - 1,$$

$$\gamma_{ab} = G_{\mu\nu} \partial_{a}X^{\mu} \partial_{b}X^{\nu}$$

$$= G_{ab} + G_{ij} \partial_{a}\Omega^{i} \partial_{b}\Omega^{j}$$

$$= G_{ab} + R^{2} \sinh^{2}\rho G_{ij}^{1} \partial_{a}\Omega^{i} \partial_{b}\Omega^{j}$$

$$= R^{2} \left\{ \begin{pmatrix} -\cosh^{2}\rho & \\ & 1 \end{pmatrix} + \sinh^{2}\rho \begin{pmatrix} (\partial_{a}\Omega)^{2} & \partial_{a}\Omega \cdot \partial_{b}\Omega \\ \partial_{b}\Omega \cdot \partial_{a}\Omega & (\partial_{b}\Omega)^{2} \end{pmatrix} \right\}$$
(5)

Here  $\partial_a \Omega \cdot \partial_b \Omega \equiv \partial_a \Omega^i \partial_b \Omega_i \equiv G^1_{ij} \partial_a \Omega^i \partial_b \Omega^j$ , and we have:

$$\det \gamma_{ab} = (R^2)^2 \left\{ \sinh^4 \rho \, \det \left( \partial_a \Omega^i \partial_b \Omega_i \right) + \sinh^2 \rho \left( (\partial_a \Omega)^2 - (\partial_b \Omega)^2 \cosh^2 \rho \right) - \cosh^2 \rho \right\}, \tag{6}$$

$$\sqrt{-\det \gamma_{ab}} = R^2 \left\{ \cosh^2 \rho - \sinh^2 \rho \left( (\partial_a \Omega)^2 - (\partial_b \Omega)^2 \cosh^2 \rho \right) - \sinh^4 \rho \, \det \left( \partial_a \Omega^i \partial_b \Omega_i \right) \right\}^{1/2}$$

Mark the end points of the string with  $\rho = r(t)$ , then the total length of such closed folded string is  $\ell = 4r$ . We then have:

$$S = -4TR^2 \int dt \int_0^r d\rho \sqrt{\cosh^2 \rho - \sinh^2 \rho \left( (\partial_a \Omega)^2 - (\partial_b \Omega)^2 \cosh^2 \rho \right) - \sinh^4 \rho \det \left( \partial_a \Omega^i \partial_b \Omega_i \right)}$$
(7)

Further simplification comes from the fact that, due to rotational symmetry, the string's motion can be restricted in a plane where its position is characterized by some angle  $\theta = \Omega^{i_0} \in \{\Omega^i\}_i$ . In this case other angle parameters  $\Omega^i|_{i \neq i_0} = 0$ , and the action is further reduced to:

$$S = -4TR^2 \int dt \int_0^r d\rho \sqrt{\cosh^2 \rho - \sinh^2 \rho \left( (\partial_a \theta)^2 - (\partial_b \theta)^2 \cosh^2 \rho \right)} = \int dt \int_0^r d\rho \, \mathcal{L}, \tag{8}$$

$$\mathcal{L} = -4TR^2 \sqrt{\cosh^2 \rho - \omega^2 \sinh^2 \rho}, \quad \omega = \partial_t \theta, \, \partial_\rho \theta = 0$$
 (9)

We consider the special solution  $\theta = \omega t$ , while in general the endpoint r = r(t) could be dynamical; variation of the action w.r.t. r(t) gives<sup>1</sup>:

$$0 = \delta S = -4TR^2 \int dt \int_{r}^{r+\delta r} d\rho \sqrt{\cosh^2 \rho - \omega^2 \sinh^2 \rho} = -4TR^2 \int dt \sqrt{\cosh^2 r - \omega^2 \sinh^2 r} \, \delta r \,, \quad (10)$$

$$\omega^2 = \frac{\cosh^2 r}{\sinh^2 r} = \coth^2 r \tag{11}$$

Note that if  $\omega$  is constant, then r must be fixed by (11). Taking  $\theta$  as the only dynamical variable, it is then straight-forward to write the energy E and angular momentum J for such folded closed string:

$$\omega = \dot{\theta}, \quad \Pi = \frac{\partial \mathcal{L}}{\partial \omega} = 4TR^2 \frac{\omega \sinh^2 \rho}{\sqrt{\cosh^2 \rho - \omega^2 \sinh^2 \rho}},$$
 (12)

$$J = \int_0^r \mathrm{d}\rho \,\Pi = 4TR^2 \int_0^r \mathrm{d}\rho \,\frac{\omega \sinh^2\rho}{\sqrt{\cosh^2\rho - \omega^2 \sinh^2\rho}},\tag{13}$$

$$E = \int_0^r d\rho \left( \Pi \omega - \mathcal{L} \right) = 4TR^2 \int_0^r d\rho \, \frac{\cosh^2 \rho}{\sqrt{\cosh^2 \rho - \omega^2 \sinh^2 \rho}},\tag{14}$$

In the large string limit,  $r \to \infty$ ,  $\omega = \coth r \to 1$ . Expand in terms of  $\epsilon = \omega - 1 > 0$ , we find that  $r = \frac{1}{2} \ln \left(1 + \frac{2}{\epsilon}\right) \sim \frac{1}{2} \ln \frac{2}{\epsilon}$ , or alternatively,  $e^{2r} \cdot \epsilon \sim 2$ . With some help from Mathematica<sup>TM</sup>, we get:

$$E - J = 4TR^{2} \int_{0}^{r} d\rho \frac{\cosh^{2}\rho - \omega \sinh^{2}\rho}{\sqrt{\cosh^{2}\rho - \omega^{2} \sinh^{2}\rho}} = 4TR^{2} \int_{0}^{r} d\rho \left(1 + \frac{\epsilon^{2}}{8} \sinh^{2}(2\rho) + \mathcal{O}(\epsilon^{3})\right)$$

$$= 4TR^{2} \left(r\left(1 - \frac{\epsilon^{2}}{16} + \mathcal{O}(\epsilon^{3})\right) + \mathcal{O}(1)\right) = \left(2TR^{2} \ln \frac{2}{\epsilon}\right) \left(1 - \frac{\epsilon^{2}}{16} + \mathcal{O}(\epsilon^{3})\right)$$

$$\sim 2TR^{2} \left(\ln \frac{2}{\epsilon}\right)$$
(15)

Similarly,  $J \sim 4TR^2 \int_0^r d\rho \sinh^2 \rho \sim TR^2(\frac{2}{\epsilon})$ , this gives:

$$E - J \sim 2TR^2 \ln \frac{J}{TR^2} \tag{16}$$

<sup>&</sup>lt;sup>1</sup>The above reasoning is confirmed in e.g. arXiv:hep-th/0204051.

## 3 Special Conformal Transformations:

$$x^{\mu} \xrightarrow{K(a)} \tilde{x}^{\mu} = \frac{x^{\mu} + x^2 a^{\mu}}{1 + 2a \cdot x + a^2 x^2}$$
 (17)

(a) Under special conformal transformation K(a), metric  $\delta_{\mu\nu} \mapsto g_{\mu\nu}$  while:

$$g_{\alpha\beta} \,\mathrm{d}\tilde{x}^{\alpha} \,\mathrm{d}\tilde{x}^{\beta} = \delta_{\mu\nu} \,\mathrm{d}x^{\mu} \,\mathrm{d}x^{\nu} \,, \quad g_{\alpha\beta} = \delta_{\mu\nu} \frac{\partial x^{\mu}}{\partial \tilde{x}^{\alpha}} \frac{\partial x^{\nu}}{\partial \tilde{x}^{\beta}}$$
 (18)

To calculate this we have to know the inverse transformation  $x = K^{-1}(a)\tilde{x}$ . First, notice the following decomposition<sup>2</sup> of K(a):

$$\tilde{x}^{\mu} = \frac{\frac{x^{\mu}}{x^{2}} + a^{\mu}}{\frac{1}{x^{2}} + \frac{2a \cdot x}{x^{2}} + a^{2}} = \frac{\frac{x^{\mu}}{x^{2}} + a^{\mu}}{\left|\frac{x^{\mu}}{x^{2}} + a^{\mu}\right|^{2}},\tag{19}$$

i.e. 
$$K(a): x^{\mu} \xrightarrow{I} \frac{x^{\mu}}{x^{2}} \xrightarrow{T(a)} y^{\mu} = \frac{x^{\mu}}{x^{2}} + a^{\mu} \xrightarrow{I} \tilde{x}^{\mu} = \frac{y^{\mu}}{y^{2}},$$
 (20)

i.e. 
$$\frac{\tilde{x}^{\mu}}{\tilde{x}^2} = \frac{y^{\mu}}{y^2} / \frac{1}{y^2} = y^{\mu} = \frac{x^{\mu}}{x^2} + a^{\mu}$$
 (21)

From (21), we see that the transformation parameter  $a^{\mu}$  composes linearly: K(b) K(a) = K(a+b), therefore  $K^{-1}(a) = K(-a)$ , and we have:

$$x^{\mu} = K(-a)\,\tilde{x}^{\mu} = \frac{\tilde{x}^{\mu} - \tilde{x}^2 a^{\mu}}{1 - 2a \cdot \tilde{x} + a^2 \tilde{x}^2} = \frac{\tilde{y}^{\mu}}{y^2},\tag{22}$$

$$\frac{\partial x^{\mu}}{\partial \tilde{x}^{\alpha}} = \frac{\partial x^{\mu}}{\partial \tilde{y}^{\sigma}} \frac{\partial \tilde{y}^{\sigma}}{\partial \tilde{x}^{\alpha}} = \left(\frac{\partial}{\partial \tilde{y}^{\sigma}} \frac{\tilde{y}^{\mu}}{\tilde{y}^{2}}\right) \frac{\partial}{\partial \tilde{x}^{\alpha}} \left(\frac{\tilde{x}^{\sigma}}{\tilde{x}^{2}} - a^{\sigma}\right) = \left(\frac{\partial}{\partial \tilde{y}^{\sigma}} \frac{\tilde{y}^{\mu}}{\tilde{y}^{2}}\right) \left(\frac{\partial}{\partial \tilde{x}^{\alpha}} \frac{\tilde{x}^{\sigma}}{\tilde{x}^{2}}\right) \\
= \left(\tilde{y}^{2} \delta^{\mu}_{\sigma} - 2\tilde{y}^{\mu} \tilde{y}_{\sigma}\right) \left(\tilde{x}^{2} \delta^{\sigma}_{\alpha} - 2\tilde{x}^{\sigma} \tilde{x}_{\alpha}\right) / \left(\tilde{y}^{4} \tilde{x}^{4}\right), \tag{23}$$

$$g_{\alpha\beta} \stackrel{\underline{(18)}}{=\!\!\!=\!\!\!=\!\!\!=} \delta_{\mu\nu} \left( \tilde{y}^2 \delta_{\sigma}^{\mu} - 2 \tilde{y}^{\mu} \tilde{y}_{\sigma} \right) \left( \tilde{x}^2 \delta_{\alpha}^{\sigma} - 2 \tilde{x}^{\sigma} \tilde{x}_{\alpha} \right) \left( \tilde{y}^2 \delta_{\rho}^{\nu} - 2 \tilde{y}^{\nu} \tilde{y}_{\rho} \right) \left( \tilde{x}^2 \delta_{\beta}^{\rho} - 2 \tilde{x}^{\rho} \tilde{x}_{\beta} \right) / \left( \tilde{y}^8 \tilde{x}^8 \right)$$

$$\stackrel{\underline{\sum_{\mu,\nu}}}{=\!\!\!=\!\!\!=\!\!\!=} \tilde{y}^{-4} \delta_{\sigma\rho} \left( \tilde{x}^2 \delta_{\alpha}^{\sigma} - 2 \tilde{x}^{\sigma} \tilde{x}_{\alpha} \right) \left( \tilde{x}^2 \delta_{\beta}^{\rho} - 2 \tilde{x}^{\rho} \tilde{x}_{\beta} \right) / \tilde{x}^8$$

$$\stackrel{\underline{\sum_{\sigma,\rho}}}{=\!\!\!=\!\!\!=} \tilde{y}^{-4} \tilde{x}^{-4} \delta_{\alpha\beta}$$

$$(24)$$

We see that  $g_{\alpha\beta} = f(x) \, \delta_{\alpha\beta}$ , with coefficient:

$$f(x) = \tilde{y}^{-4}\tilde{x}^{-4} = \frac{(20)}{\tilde{x}^4} = \frac{x^4}{\tilde{x}^4} = \frac{(21)}{\tilde{x}^4} \left(1 + 2a \cdot x + a^2 x^2\right)^2$$
 (25)

 $\Box_{(a)}$ 

(b) In 2D with  $z=x^1+ix^2,~x^\mu\sim(z,\bar{z}),$  we see from (21) that:

$$\frac{x^{\mu}}{x^{2}} \sim \frac{z}{|z|^{2}} = \frac{1}{\bar{z}} \longmapsto \frac{1}{\bar{z}} + a, \quad \text{i.e.} \quad z \longmapsto w = \frac{1}{\frac{1}{z} + \bar{a}} = \frac{z}{1 + z\bar{a}}$$
 (26)

Expand in the  $\bar{a} \to 0$  limit, we find that  $w = z (1 - z\bar{a} - \cdots) \sim z - z^2\bar{a}$ , i.e. it is generated by:

$$K_{\bar{z}} = -z^2 \partial_z = -z^2 \partial, \quad \partial \equiv \partial_z$$
 (27)

<sup>&</sup>lt;sup>2</sup>See Di Francesco et al, and also github.com/davidsd/ph229.

Note that when considering non-holomorphic functions, we have to consider  $(z, \bar{z})$  as two independent variables; hence the anti-holomorphic transformation  $\bar{z} \mapsto \bar{w} = \frac{\bar{z}}{1+\bar{z}a} \sim \bar{z} - \bar{z}^2 a$  provides another degree of freedom, namely:

$$K_{\mu} \sim \left(K_{\bar{z}} = -z^2 \partial, K_z = -\bar{z}^2 \bar{\partial}\right),$$
 (28)  
 $\partial \equiv \partial_z, \ \bar{\partial} \equiv \partial_{\bar{z}}$ 

Similarly, for translation  $z \mapsto z + a$  and its conjugate, we have  $P_{\mu} \sim (P_z = \partial, P_{\bar{z}} = \bar{\partial})$ . However, dilation and rotation are both encoded in a complex rescaling  $z \mapsto \lambda z$ ,  $\lambda = re^{i\theta} \in \mathbb{C}$ ; we have:

$$z \mapsto \lambda z, \quad \lambda = re^{i\theta} \in \mathbb{C}, \quad \begin{cases} \delta r &\longleftrightarrow D = z \,\partial + \bar{z}\,\bar{\partial}, \\ \delta \theta &\longleftrightarrow M = i\left(z \,\partial - \bar{z}\,\bar{\partial}\right), \end{cases}$$
 (29)

In summary, we have  $\operatorname{span}_{\mathbb{R}} \{ P_{\mu}, K_{\mu}, D, M \} = \mathfrak{so}(3, 1)$  generating the "global" transformation subgroup of the 2D conformal group; here, the  $\mathfrak{so}(3, 1)$  boost is a linear combination<sup>3</sup> of  $P_{\mu}$  and  $K_{\mu}$ . More specifically, in 2D any holomorphic or anti-holomorphic function gives a conformal transformation, hence the (classical) 2D conformal group is generated by:

$$\ell_m = z^{m+1}\partial, \quad \bar{\ell}_m = \bar{z}^{m+1}\bar{\partial}, \quad m \in \mathbb{Z}$$
 (30)

i.e. the Witt algebra (or Virasoro algebra  $\operatorname{Vir}_c$  with c=0). It is clear that a (complexified)  $\mathfrak{so}(3,1)$  lives inside  $\operatorname{Vir}_c$ , i.e.,

$$\mathfrak{so}(3,1)^{\mathbb{C}} = \operatorname{span}_{\mathbb{C}} \{ P_{\mu}, K_{\mu}, D, M \}$$

$$= \operatorname{span}_{\mathbb{C}} \{ \ell_{m}, \bar{\ell}_{m} \mid m = 0, \pm 1 \} = \mathfrak{sl}(2, \mathbb{R})^{\mathbb{C}} \oplus_{\mathbb{C}} \mathfrak{sl}(2, \mathbb{R})^{\mathbb{C}} \subset \operatorname{Vir}_{c}$$
(31)

$$S = \frac{1}{2\pi} \int d^2 z \, b \, \bar{\partial} c \tag{32}$$

Stress tensor of a theory can be obtained via variation over the metric, or equivalently, over the fields  $\phi^i$  with  $\delta\phi$  induced by some *local* spacetime translation  $x^{\mu} \mapsto x^{\mu} + \delta x^{\mu}$ ,  $\delta x^{\mu} = \epsilon(x) a^{\mu}$ . Here  $\epsilon(x)$  is any compactly supported bump function, centered around some point  $x_0$ .

In 2D, we have  $\mu=z,\bar{z};$  for  $\phi(z,\bar{z})$  with conformal weight  $(h,\bar{h}),$  consider  $z\mapsto z',\bar{z}\mapsto\bar{z}'.$  For convenience, let's first consider a generic variation  $\delta z=\epsilon(z,\bar{z})$  before restricting to spacetime translation; we have:

$$\phi'(z',\bar{z}') = \left(\frac{\mathrm{d}z'}{\mathrm{d}z}\right)^{-h} \left(\frac{\mathrm{d}\bar{z}'}{\mathrm{d}\bar{z}}\right)^{-\bar{h}} \phi(z,\bar{z}),\tag{33}$$

$$\tilde{\delta}\phi = \left(-h\,\partial\epsilon - \bar{h}\,\bar{\partial}\bar{\epsilon}\right)\phi,\tag{34}$$

$$\delta\phi = \tilde{\delta}\phi - \frac{\partial\phi}{\partial x^{\mu}} \,\delta x^{\mu} = \left(-h\,\partial\epsilon - \bar{h}\,\bar{\partial}\bar{\epsilon}\right)\phi - \epsilon\,\partial\phi - \bar{\epsilon}\,\bar{\partial}\phi,\tag{35}$$

Here we use  $\tilde{\delta}\phi$  to denote the "internal" variation related to the conformal weights.

<sup>&</sup>lt;sup>3</sup>See e.g. github.com/davidsd/ph229.

Note that  $\phi = b$ , c are anti-commuting Grassmann numbers, variation of the action gives:

$$\delta S[b, c, \delta b, \delta c] = \frac{1}{2\pi} \int d^2 z \left( \delta b \,\bar{\partial} c + b \,\bar{\partial} \,\delta c \right)$$

$$= \frac{1}{2\pi} \int d^2 z \left( -\bar{\partial} c \,\delta b - \bar{\partial} b \,\delta c \right) + \frac{1}{2\pi} \int d^2 z \,\bar{\partial} (b \,\delta c) \tag{36}$$

For  $unknown\ b, c$  and arbitary  $\delta b$ ,  $\delta c$ , the second term is reduced to a boundary term at infinity and can be dropped; imposing  $\delta S = 0$  gives the equation of motion (EOM):  $\bar{\partial} b = \bar{\partial} c = 0$ .

On the other hand, for on-shell b, c and compactly supported  $\phi = \delta b$ ,  $\delta c$  given in (35), the first term in (36) vanishes while  $\delta S_0 = 0$  still holds; this gives:

$$0 = \delta S_0 = \frac{1}{2\pi} \int d^2 z \,\bar{\partial}(b \,\delta c) = \frac{1}{2\pi} \int d^2 z \,\bar{\partial} \left( -(1-\lambda) \,bc \,\partial \epsilon - b \,\partial c \,\epsilon \right)$$
$$= \frac{1}{2\pi} \int d^2 z \left( -(1-\lambda) \,bc \,\bar{\partial}\partial \epsilon - b \,\partial c \,\bar{\partial}\epsilon \right)$$
(37)

Here we've distributed the  $\bar{\partial}$  operator and dropped all terms that vanish automatically by EOM. Next we shall collect the  $\partial \epsilon$ ,  $\bar{\partial} \epsilon$  terms; integrating by parts on the first integrand gives:

$$0 = \delta S_0 = \frac{1}{2\pi} \int d^2 z \left( (1 - \lambda) \,\partial(bc) - b \,\partial c \right) \bar{\partial} \epsilon$$

$$= \frac{1}{2\pi} \int d^2 z \left( (\partial b) \,c - \lambda \,\partial(bc) \right) \bar{\partial} \epsilon$$

$$= -\frac{1}{2\pi} \int d^2 z \,\epsilon(z, \bar{z}) \,\partial_{\bar{z}} \left( (\partial b) \,c - \lambda \,\partial(bc) \right)$$
(38)

Notice that we have obtained a conserved current using a generic  $\delta z = \epsilon(z, \bar{z}), \delta \bar{z} = \bar{\epsilon}(z, \bar{z})$ ; by setting  $\epsilon = \epsilon(z)$ , we get a energy momentum tensor<sup>4</sup>:

$$T(z) = :(\partial b) c: -\lambda \partial (:bc:)$$
(39)

Normal ordering is added manually to remove singular terms.

To compute TT OPE, we need the OPE of b(z) c(0); this is obtained by examining the following path integral, which is zero since the integrand is a total functional derivative:

$$0 = \int \mathcal{D}b \mathcal{D}c \, \frac{\delta}{\delta \phi} \left( e^{-S} \, \psi \right) \tag{40}$$

Taking  $\phi, \psi = b, c$ , this generates operator equations such as  $\bar{\partial} b(z)c(0) = 2\pi\delta^2(z,\bar{z})$ . Note that  $\bar{\partial}(\frac{1}{z}) = 2\pi\delta^2(z,\bar{z})$ , which gives:

$$b(z) c(0) \sim c(z) b(0) \sim \frac{1}{z}, \quad b(z) b(0) \sim 0 \sim c(z) c(0)$$
 (41)

With the bc OPE in hand, the TT OPE is computed directly with brute force, by repeatedly applying Wick's theorem. This gives:

$$T(z)T(0) \sim \frac{-6\lambda^2 + 6\lambda - 1}{z^4} + \cdots$$
 (42)

In general we have  $-6\lambda^2 + 6\lambda - 1 = \frac{c}{2}$ ; for  $\lambda = 2$  this gives c = -26.

<sup>&</sup>lt;sup>4</sup>Note that the energy momentum tensor obtained in this way is generally *not* unique: it can be off by a boundary term or any term that vanish on-shell; see Luboš' comment at physics.stackexchange.com/a/96100, also arXiv: 1601.03616. However, it is possible to fix this redundancy by considering *Tb* OPE and match its conformal dimension. I would like to thank 林般 for pointing this out.

## 5 Free Fermion CFT:

$$S = \int d^2 z \, \psi_i \, \bar{\partial} \psi^i, \quad \psi^i = \psi_i^*, \quad \psi_i = \psi_i(z)$$
(43)

(a) Mode expansion of such chiral fermion is given by:

$$\psi_i = \sum_{k \in \mathbb{Z} + \frac{1}{2}} \frac{b_{ik}}{z^{k + \frac{1}{2}}}, \quad b_{ik} = \frac{1}{2\pi i} \oint dz \, z^{k - \frac{1}{2}} \psi_i \tag{44}$$

Canonical quantization is achieved by simply imposing anti-commutation relations; this is justified by mapping the system onto a cylinder, then  $b_{ik}$ 's indeed map to modes on the spatial circle<sup>5</sup>. The only non-zero commutators are:

$$\left\{b_{ik}, b_a^{j\dagger}\right\} = \delta_{k+q,0} \,\delta_i^j \tag{45}$$

This gives the only non-zero 2-point functions:

$$\langle \psi_{i}(z) \psi^{j}(w) \rangle = \sum_{k,q \in \mathbb{Z} + \frac{1}{2}} \frac{1}{z^{k+\frac{1}{2}}} \frac{1}{w^{q+\frac{1}{2}}} \langle b_{ik} b_{q}^{j\dagger} \rangle$$

$$= \sum_{k,q \in \mathbb{Z} + \frac{1}{2}} \frac{1}{z^{k+\frac{1}{2}}} \frac{1}{w^{q+\frac{1}{2}}} \langle 0 | \{b_{ik}, b_{q}^{j\dagger}\} | 0 \rangle = \frac{\delta_{i}^{j}}{z - w}$$
(46)

Note that  $b_k^i |0\rangle = 0$ ,  $\forall k \ge \frac{1}{2}$ .

(b)(c) Combining two  $\psi$  expansions gives the mode expansion of  $J_i^j = : \psi_i(z) \, \psi^j(z):$ , namely:

$$J_i^{j}(z) = \sum_{k \in \mathbb{Z}} \frac{(J_i^{j})_k}{z^{k+1}}, \quad (J_i^{j})_k = \sum_{q \in \mathbb{Z} + \frac{1}{2}} :b_{iq} b_{k-q}^{j\dagger}:$$

$$(47)$$

It is in fact more convenient to obtain the JJ OPE first, and then use it to find the  $[J_0, J_0]$  mode commutator<sup>6</sup>; note that  $\psi_i(z) \psi^j(w)$  contraction gives  $\frac{\delta_i^j}{z-w}$ , we have:

$$J_i^{\ j}(z) J_k^{\ l}(0) \sim \frac{\delta_i^l \delta_k^j}{z^2} + \frac{\delta_k^j J_i^{\ l}(0) - \delta_i^l J_k^{\ j}(0)}{z}, \tag{48}$$

$$\left[ (J_i^{\ j})_0, (J_k^{\ l})_0 \right] = \frac{1}{(2\pi i)^2} \oint_0 \mathrm{d}w \oint_w \mathrm{d}z \, J_i^{\ j}(z) \, J_k^{\ l}(w) = \delta_i^l \, (J_k^{\ j})_0 - \delta_k^j \, (J_i^{\ l})_0 \tag{49}$$

(d) Similar to bc CFT, we have:

$$T(z) = \frac{1}{2} \left( : \psi_i \, \partial \psi^i : - : \partial \psi_i \, \psi^i : \right), \quad T(z) \, T(w) \sim \frac{n/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w}$$
 (50)

With each (complex) field contributing  $\frac{1}{2} \times 2$  central charge<sup>7</sup>.

 $<sup>^{5}</sup>$ This can be proven rigorously by considering operator equations like in the bc CFT problem.

 $<sup>^6\</sup>mathrm{I}$  would like to thank 谷夏 for providing this hint.

<sup>&</sup>lt;sup>7</sup>In fact a complex (Dirac) fermion can be "treated like" (dual to) a boson; this is bosonization.

(e) For real fermions, there is an additional reality condition:

$$\psi^i = \psi_i^* = \psi_i \tag{51}$$

The canonical quantization still holds without the extra adjoint, same as the 2-point function:

$$\langle \psi_i(z) \, \psi_j(w) \rangle = \frac{\delta_{ij}}{z - w}$$
 (52)

Similar holds for  $J_{ij} = : \psi_i \psi_j :$  and its OPE, but we no longer need to distinguish upper/lower indices; we have:

$$J_{ij}(z) J_{kl}(0) \sim \frac{-\delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk}}{z^2} + \frac{-\delta_{ik}J_{jl}(0) + \delta_{il}J_{jk}(0) + \delta_{jk}J_{il}(0) - \delta_{jl}J_{ik}(0)}{z}$$
(53)

$$[(J_{ij})_0, (J_{kl})_0] = -\delta_{ik}(J_{jl})_0 + \delta_{il}(J_{jk})_0 + \delta_{jk}(J_{il})_0 - \delta_{jl}(J_{ik})_0$$
(54)

This is precisely the  $\mathfrak{o}(n)$  algebra.
